## **CHAPTER 9**

### **PROGRAMMABLE COMMUNICATING THERMOSTATS (PCT)**

#### **ED QUIROZ**

##### **I. INTRODUCTION AND SUMMARY**

San Diego Gas and Electric (SDG&E) is proposing to deploy an AMI system that includes integrating programmable communicating thermostats (PCT) as part of its strategy.

SDG&E has proposed to deploy PCT devices between 2009 thru 2013 at approximately 16,000 small and medium commercial and industrial (C+I) customer premises. These customers are assumed to have a peak demand of 200kw or less.

##### **II. PROGRAMMABLE COMMUNICATING THERMOSTATS**

As part of SDG&E's July 14<sup>th</sup>, 2006 supplemental filing, the company is now identifying programmable communicating thermostats (PCTs) as part of its business case for AMI. The PCTs are expected to be deployed between 2009 thru 2013 at approximately 16,000 small and medium commercial and industrial (C+I) customer premises. These customers are assumed to have a peak demand of 200 kW or less. Because these premises typically have multiple PCTs per location, the actual PCT total may be closer to approximately 57,000.

The California Energy Commission is in the process of updating its Title 24 standards to include PCTs in the 2008 revision. SDG&E assumes that the deployed communication network that becomes part of the AMI system can also be used for the PCT communication, rather than propose a specific independent technical solution.

DRA feels that any discussion of demand response (DR) must take seriously the potential to automate customer response to price signals. The potential impact of

1 PCT on demand response is clear when reading the 2005 Statewide Pricing Pilot  
2 (SPP) Report<sup>1</sup>. Though this report was primarily concerned with estimating the  
3 price elasticity of electricity, with secondary analysis of customer preferences, the  
4 report contains many illustrations of the PCT as a powerful DR tool. For example,  
5 the SPP report measured a peak period load reduction of 27% for one test population  
6 in SDG&E's territory and attributed 2/3 of that group's savings to PCT systems<sup>2</sup>.  
7 In fact, the load reduction achieved by the PCT equipped peak test population in  
8 SDG&E's territory was the largest measured by the SPP Report.

9 Partially explaining the importance of PCTs is the correlation between air  
10 conditioning use and peak energy consumption. California's peak energy use days  
11 correspond to the hottest days of the year. This is because of the fact that on the  
12 hottest days of the year, Californians run their air conditioners longer than during the  
13 rest of the year to cool their homes and businesses. This air conditioning load  
14 exhibits higher demand elasticity than base uses such as lighting; this can be seen by  
15 examining the demand elasticities of customers in cooler and warmer climate zones<sup>3</sup>.  
16 Affording customers access to tools that control that portion of their load, which they  
17 would preferentially shed, should be a high priority – particularly when the PCT  
18 controls the single largest category of electrical load during peak periods.

19 DRA understands that open PCT standards, as currently proposed to be added  
20 to Title 24 standards will allow residential ratepayers to independently purchase and  
21 install PCT devices in their homes. The PCT devices that residential ratepayers will  
22 be able to buy in hardware stores will be instrumental in their achieving significant  
23 financial savings under any time-differentiated tariff. Furthermore, ratepayer access  
24 to an open-standard, competitively priced, automated thermostat (PCT) potentially  
25 reduces the challenging and cumbersome process currently associated with

1 participating in a CPP or RTP pricing tariff. Future proceedings can measure the  
2 wisdom of subsidizing the purchase and installation of PCT in customer homes, but  
3 the communications network and customer education of this communications function  
4 is an essential part of any CPP or RTP pricing tariff plan.

### 5 **III. RISK MITIGATION**

6 SDG&E provided a table, PP11-1 that provides cost information. A line item  
7 for the total PCTs O&M shows an amount of \$24,857,000 projected over what  
8 appears to be a 30 year period through 2038. Very little support documentation is  
9 given to explain the total amount or how it is allocated during the time period.  
10 Additionally, SDG&E projects a \$75/PCT installation cost and an additional \$25/PCT  
11 cost for each additional PCT installed at the same site. While this number is derived  
12 from experience gained from a previous SDG&E Smart Thermostat Program, no  
13 mention is made as to potential cost reductions that might be had as PCT scale-up  
14 occurs.

### 15 **IV. CONCLUSIONS**

16 SDG&E has provided a description, as part of its July 14<sup>th</sup> supplemental filing,  
17 of approximately 16,000 PCTs that will be part of the project. Much of the  
18 performance specifications for the PCT deployment is still unknown because of  
19 current development and evolving specifications as part of the California Energy  
20 Commission's (CEC) Title 24 2008 revision process. Nevertheless, DRA believes  
21 that the PCT deployment has the potential to attract an increased participation and  
22 greater customer DR response for those customers on dynamic tariffs.
